

# Marcus Oxidized Polyethylene Wax for Water based Emulsions

Pressure Direct  
Emulsification of  
Marcus 3400 and 3500  
Polyethylene

## Pressure Direct Anionic Emulsion Preparation

**The pressure direct emulsification technique involves charging all ingredients into an agitated pressure vessel and making the emulsion under pressure.**

**This process has several advantages over atmospheric emulsification:**

- Produces an emulsion with greater uniformity and consistency
- Reduces batch cycle time
- Facilitates emulsions with higher solids
- Eliminates or reduces volatilization of key raw materials

**This latter point allows for a greater variety of raw materials to be**

### Anionic Formulation (25% solids)

	<u>Percent</u>
Marcus M3500 or M3400	19.1
Fatty Acid	3.8
Amine	3.8
Water	65

### Comments:

Fatty acid is Oleic or tall oil. Morpholine can be used for amine.

### Procedure:

Charge water to the reactor and then add other ingredients while agitating. Seal the reactor while continuing to agitate and commence heating to a temperature of 125-135°C. Maintain temperature and pressure with agitation for 15-30 minutes. Remove heating and begin cooling. For best results cooling is done quickly (shock cooling) while releasing pressure through an external heat exchanger such as a coil or plate heat exchanger. Rapid cooling, especially through the transition point of the wax, ensures a fine particle size emulsion is formed..

Following cooling to room temperature a bactericide can be added to aid shelf life of the emulsion. The emulsion should then be discharged and filtered.
